ABC Allows Us to Count Squarefrees

Andrew Granville

Dedicated to the memory of Paul Erdős

1 Introduction

For any given polynomial $f(x) \in \mathbb{Z}[x]$, we investigate what proportion of the integers $f(1), f(2), f(3), \ldots$ are squarefree.\(^1\)

The values, at integers, taken by certain polynomials, are always divisible by a square for not entirely obvious reasons (for example, $n(n - 1)(n - 2)(n - 3)$ is always divisible by 8). We take care of this as follows: Let $B$ be the greatest common divisor of $f(n)$, $n \in \mathbb{Z}$; and let $B'$ be the smallest divisor of $B$ such that $B/B'$ is squarefree. Then $f(n)/B'$ can feasibly be squarefree for various integers $n$.

The study of this question has a rich history. It was Erdős [5] who established that if $f(x)$ has degree $\leq 3$, and $B = 1$, then there are infinitely many integers $n$ for which $f(n)$ is squarefree. There are no such results proven unconditionally for any irreducible polynomials of degree $> 3$, though Browkin, Filaseta, Greaves, and Schinzel [2] did prove such a result for all cyclotomic polynomials under the assumption of the abc-conjecture.

Similar results for binary homogenous forms, whose irreducible factors have low degree, were established by Hooley [14], by Greaves [13], and by Browkin, Filaseta, Greaves, and Schinzel [2]. Here we show that these questions can be completely answered, as a consequence of the abc-conjecture, which we now describe as follows.

Received 30 March 1998. Revision received 24 July 1998.
Communicated by Enrico Bombieri.
\(^1\)That is, not divisible by the square of a prime.
The abc-conjecture (Oesterlé, Masser, Szpiro). Fix $\varepsilon > 0$. If $a, b, c$ are coprime positive integers satisfying $a + b = c$, then

$$c \ll \varepsilon \cdot N(a, b, c)^{1+\varepsilon},$$

where $N(a, b, c)$ is the product of the distinct primes dividing $abc$. \hfill \Box

This conjecture has many extraordinary consequences (such as Fermat's last theorem is true—other than for at most finitely many counterexamples). Following constructions of Belyi [1] and Elkies [3], and a little bit of elementary sieving, we shall prove several results about the distribution of squarefree integers, as a consequence of the abc-conjecture.

**Theorem 1.** Suppose that $f(x) \in \mathbb{Z}[x]$, without any repeated roots. Let $B$ be the largest integer which divides $f(n)$ for all integers $n$, and select $B'$ to be the smallest divisor of $B$ for which $B/B'$ is squarefree. If the abc-conjecture is true, then there are $\sim c_\varepsilon N$ positive integers $n \leq N$ for which $f(n)/B'$ is squarefree, where $c_\varepsilon > 0$ is a positive constant, which we determine as follows:

$$c_\varepsilon = \prod_{p \text{ prime}} \left(1 - \frac{\omega_f(p)}{p^{2+\varepsilon q_p}}\right),$$

where, for each prime $p$, we let $q_p$ be the largest power of $p$ which divides $B'$ and let $\omega_f(p)$ denote the number of integers $a$ in the range $1 \leq a \leq p^{2+\varepsilon q_p}$ for which $f(a)/B' \equiv 0 \pmod{p^2}$. \hfill \Box

This result can be proved unconditionally if $f$ has degree $\leq 2$ using the sieve of Eratosthenes. It was proved unconditionally by Hooley [14] for $f$ of degree 3.

Theorem 1 can be viewed as verifying the appropriate "local-global" principle: The factors

$$\left(1 - \frac{\omega_f(p)}{p^{2+\varepsilon q_p}}\right)$$

represent the proportion of integers $n$, for which $f(n)/B'$ is not divisible by $p^2$. We have thus shown that the proportion of positive integers $n$, for which $f(n)/B'$ is squarefree, is exactly the product, over all primes $p$, of these local densities.

As we noted above, there has also been considerable interest in squarefree values of binary forms. The proof of the following result is a modification of that of Theorem 1, though, strangely, it involves the classification of the finite subgroups of PGL(2, Q) (see the Appendix).
Theorem 2. Suppose that \( f(x, y) \in \mathbb{Z}[x, y] \) is homogenous, without any repeated linear factors. Let \( B \) be the largest integer which divides \( f(m, n) \) for all pairs of integers \( m, n \); and select \( B' \) to be the smallest divisor of \( B \) for which \( B/B' \) is squarefree. We will assume that \( M, N \to \infty \) in the following.\(^2\) If the abc-conjecture is true, then there are \( \sim c'_1 MN \) pairs of positive integers \( m \leq M, \ n \leq N \) for which \( f(m, n)/B' \) is squarefree, where \( c'_1 > 0 \) is a positive constant, which we determine as follows:

\[
c'_1 = \prod_{p \text{ prime}} \left(1 - \frac{\omega'(p)}{p^{4+2q_p}}\right),
\]

where, for each prime \( p \), we let \( q_p \) be the largest power of \( p \) which divides \( B' \), and let \( \omega'(p) \) denote the number of pairs of integers \( a, b \) in the range \( 1 \leq a, b \leq p^{2+\omega} \) for which \( f(a, b)/B' \equiv 0 \pmod{p^2} \).

We again note the "local-global" principle in action here. Theorems 1 and 2 above carry over, with no significant changes, to arbitrary number fields \( K \); that is, one can state analogous results for \( f(x) \in K[x] \) and \( f(x, y) \in K[x, y] \), though one needs to give an appropriate formulation of the abc-conjecture in number fields.\(^3\)

A similar proof allows us to solve various questions about the distribution of squarefree numbers: Let \( s_1 = 1 < s_2 = 2 < s_3 = 3 < s_4 = 5 < \ldots \) be the sequence of squarefree numbers. Filaseta and Trifonov [9] have shown that consecutive squarefree numbers cannot get too far apart; that is, \( s_{n+1} - s_n \ll s_n^{1/5} \log(s_n) \). Assuming the abc-conjecture, we can get a sharper result.

Theorem 3. Suppose that the abc-conjecture is true and fix \( \varepsilon > 0 \). Then, once \( x \) is sufficiently large, there must be a squarefree integer in the interval \( (x, x + x^\varepsilon) \). In other words, \( s_{n+1} - s_n \ll x^{1/5} \).

Let \( a_1 < a_2 < \ldots < a_k \) be a fixed set of positive integers. From the sieve of Eratosthenes, one can show that there are \( \sim \gamma_x \) integers \( m \leq x \) for which \( m, m + a_1, m + a_2, \ldots, m + a_k \) are all squarefree, where the constant

\[
\gamma_x = \gamma(a_1, a_2, \ldots, a_k) = \prod_{p} \left(1 - \frac{\omega_x(p)}{p^2}\right),
\]

and \( \omega_x(p) \) is the number of distinct residue classes in the set \( 0, a_1, \ldots, a_k \pmod{p^2} \). Thus there are \( \sim \delta_x \) squarefree integers \( n \leq x \) for which the next largest squarefree integer is

---

\(^2\)If one of these variables does not go to infinity, then the desired result may be obtained by summing over applications of Theorem 1.

\(^3\)Vojta [22, p. 84] showed how to formulate the abc-conjecture in arbitrary number fields, from which Elkies [3] elegantly deduced Faltings' theorem.
\[ \delta_t := \sum_{l \in \{1, 2, \ldots, k-1\}} (-1)^l n_{l(t)} \text{,} \]

which is easily proved using the inclusion-exclusion formula.

It was Erdős [4] who began the study of the average moments of \( s_{n+1} - s_n \), that is, 
\[ (1/x) \sum_{s_n \leq x} (s_{n+1} - s_n)^A \],
showing that this tends to a limit as \( x \to \infty \) for \( 0 \leq A \leq 2 \); this was extended to \( A \leq 3 \) by Hooley [15], to \( A \leq 29/9 \) by Filaseta [8], and to \( A \leq 43/13 \) by Filaseta and Trifonov [10]. If we define \( S(x; t) \) to be the number of \( s_n \leq x \) for which \( s_{n+1} - s_n = t \), then the above sum equals \( (1/x) \sum_{t \geq 1} S(x; t)t^A \). In Section 6, we will deduce that

\[ \sum_{T \leq t < 2T} S(x; t) \ll A x/T^{A+1} \tag{2} \]

from the abc-conjecture. Therefore

\[ \frac{1}{x} \sum_{s_n \leq x} (s_{n+1} - s_n)^A = \frac{1}{x} \sum_{1 \leq t \leq T} S(x; t)t^A + O \left( \frac{1}{T} \right) \to \sum_{t \geq 1} \delta_t t^A + O \left( \frac{1}{T} \right) \]

as \( x \to \infty \). Now letting \( T \to \infty \), and defining \( \beta_A := \sum_{t \geq 1} \delta_t t^A \), we deduce the following theorem.

**Theorem 4.** Suppose that the abc-conjecture is true. For any fixed \( A > 0 \), there exists a constant \( \beta_A > 0 \) such that

\[ \sum_{s_n \leq x} (s_{n+1} - s_n)^A \sim \beta_A x. \]

**Remark.** In fact, Theorem 4 follows from Theorem 3 as was shown in [8]. We give a simplified version of that deduction here.

All of these results rely on the following consequence of Belyi's theorem, first noted by Elkies [3, 26] and Langevin [17] (a proof is also sketched in Section 3).

**Theorem 5.** Assume that the abc-conjecture is true. Suppose that \( f(x, y) \in \mathbb{Z}[x, y] \) is homogenous, without any repeated linear factors. Fix \( \epsilon > 0 \). Then, for any coprime integers \( m \) and \( n \),

\[ \prod_{\text{primes } p \mid f(m, n)} p \gg \max(|m|, |n|)^{\deg(f) - 2 - \epsilon}. \]

Note that the constant implicit in “\( \gg \)” depends on both \( \epsilon \) and \( f \). 

**Remark.** The abc-conjecture is the case \( f(x, y) = xy(x + y) \) of the estimate in Theorem 5. Roth's theorem also follows easily from this estimate, since \( |f(m, n)| \) is at least as large as the product of the primes dividing it.
Theorem 5 is "best possible" for any such $f(x, y) \in \mathbb{Z}[x, y]$ of degree $> 2$; that is, one can always find coprime integers $m, n$ with $\prod_{p|f(m, n)} p \ll \max(|m|, |n|)^{\deg f - 2}$. One can prove this via a standard "pigeonhole principle" argument: Let $\ell$ be the smallest prime which does not divide the discriminant of $f(x, 1)$, and such that there exists an integer $t \not \equiv 0 \pmod{\ell}$ with $f(t, 1) \equiv 0 \pmod{\ell}$. We can use the Hensel lifting lemma to determine $t_k$ such that $f(t_k, 1) \equiv 0 \pmod{\ell^k}$ for any given positive integer $k$. There are more than $\ell^{2k}$ integers $a - bt_{2k}$ with $0 \leq a, b \leq \ell^k$, so two of them are congruent $\pmod{\ell^{2k}}$, and we let $m - nt_{2k}$ be their difference. If $\ell^r$ is the highest power of $\ell$ dividing both $m$ and $n$ and $M = m/(m, n)$, $N = n/(m, n)$, then we find that $f(M, N) \equiv 0 \pmod{\ell^{2k-r}}$ whereas $\max(|M|, |N|)^2 \leq (\ell^k)^2 \leq \ell^{2k-r}$, establishing the result.

If we wish to consider $g(x) \in \mathbb{Z}[x]$, then we can obtain a stronger consequence of Theorem 5 than comes from simply setting $n = 1$. If $g(x)$ has degree $d$, then we let $f(x, y) = y^{d-1}g(x/y)$; thus $g(x) = f(x, 1)$, but $f$ has one higher degree than before. So now, applying Theorem 5, we obtain the following corollary.

**Corollary 1.** Assume that the abc-conjecture is true. Suppose that $g(x) \in \mathbb{Z}[x]$ has no repeated roots. Fix $\varepsilon > 0$. Then

$$\prod_{\text{primes } p | g(m)} p \gg |m|^{\deg g - 1 - \varepsilon}. \quad \square$$

(This result was also noted by Langevin [17].) By a similar counting argument to the one following Theorem 5, one can show that this result is "best possible"; that is, one can always find arbitrarily large integers $m$ with $\prod_{p|g(m)} p \ll |m|^{\deg g - 1}$.

The next result, although an immediate corollary to Theorem 5 and Corollary 1, seems to be of independent interest.

**Theorem 6.** Assume that the abc-conjecture is true. Suppose that $f(x, y) \in \mathbb{Z}[x, y]$ is homogenous, without any repeated linear factors. Fix $\varepsilon > 0$. If $q^2$ divides $f(m, n)$, for any coprime integers $m$ and $n$, then $q \ll \max(|m|, |n|)^{2+\varepsilon}$. Also, if $g(x) \in \mathbb{Z}[x]$ has no repeated roots and $q^2$ divides $g(m)$, then $q \ll |m|^{1+\varepsilon}$. \hspace{1cm} \square

We do not yet know, in general, whether this result is best possible, though we expect so.

**Conjecture.** Suppose that $f(x, y) \in \mathbb{Z}[x, y]$ is homogenous, without any repeated linear factors, of degree $\geq 4$. There exist infinitely many pairs of coprime integers $m$ and $n$, for which there is an integer $q \gg \max(|m|, |n|)^2$ with $q^2$ dividing $f(m, n)$. Similarly, for any $g(x) \in \mathbb{Z}[x]$ without repeated roots of degree $\geq 2$, there are arbitrarily large integers $m$ for which there is an integer $q \gg m$ with $q^2$ dividing $g(m)$. \hspace{1cm} \square
Using a "pigeonhole principle" argument as above, one only gets $q \gg \max(|m|, |n|)$ with $q^2$ dividing $f(m, n)$, and $q \gg \sqrt{m}$ with $q^2$ dividing $g(m)$, respectively.

We can, however, prove our conjecture when $f$ has degree 4 (and when $g$ has degree 2): Any equation $cv^2 = f(u, 1)$ describes a curve of genus 1. If this has infinitely many rational points (as must happen for well-chosen values of integer $c$), we can write them each in the form $(m/n, r/n^2)$ and then get the desired examples, since $f(m, n) = cr^2$.

The first result in Theorem 6 implies that if $f(x)$ has degree $> 4$, then there are only finitely many rational solutions to $y^k = f(x)$ for any fixed $k \geq 2$; this is a result which follows from Faltings' theorem. The second result in Theorem 6 implies that if $f(x)$ has degree $> 2$, then there are only finitely many integer solutions to $y^k = f(x)$ for any fixed $k \geq 2$; this is a result which follows from the Thue-Siegel theorem. However, we can conclude somewhat more, as follows.

An integer $n$ is called powerful if $p^2$ divides $n$ for every prime $p$ dividing $n$. The first result in Theorem 6 implies that if $f(x, y) \in \mathbb{Z}[x, y]$ has degree $> 4$, then $f(m, n)$, with $(m, n) = 1$, is powerful only finitely often. Similarly, the second result in Theorem 6 implies that if $g(x) \in \mathbb{Z}[x]$ has degree $> 2$, then $g(m)$ is powerful only finitely often.

Let $r_1 = 1 < r_2 = 4 < \ldots$ be the sequence of powerful numbers. If we let $x + y\sqrt{5} = (3 + \sqrt{5})^k$, for any integer $k$, then both $8y^2$ and $x^2 = 8y^2 + 1$ are powerful. Thus there are infinitely many integers $n$ for which $r_{n+1} - r_n = 1$. Erdős [6] conjectured that there are never three consecutive powerful numbers; that is, $r_{n+2} - r_n > 2$. It follows easily from the abc-conjecture that there are only finitely many such triples; for, if $t - 1, t, t + 1$ are all powerful, then apply the abc-conjecture to the equation $1 + (t^2 - 1) = t^2$ to get a contradiction. In fact, the abc-conjecture implies rather more.

**Theorem 7.** Assume that the abc-conjecture is true. If $r_1 = 1 < r_2 = 4 < \ldots$ is the sequence of powerful numbers, then $r_{n+2} - r_n \to \infty$ as $n \to \infty$. \hfill \Box

To prove this, suppose it is false, so that there exist integers $0 < a < b$ for which there are infinitely many integers $m$ with $m, m + a,$ and $m + b$ all powerful. But then for $g(x) = x(x + a)(x + b)$, we have $\prod_{p | g(m)} p \ll m^{3/2}$, contradicting Corollary 1.

It is an open question to try to estimate the number of $r_n \leq x$ for which $r_{n+1} - r_n = 1$, in other words, to estimate the number of pairs of consecutive powerful numbers up to $x$. The above construction gives $\gg \log x$ such pairs, and one might guess that there are $\sim c \log x$ for some constant $c > 0$.

We can also apply Corollary 1 to binomial coefficients, to get the following: For any fixed integer $k \geq 3$, there are only finitely many integers $n$ for which $\binom{n}{k}$ is powerful. In fact, Erdős and Selfridge conjectured that the only example with $3 \leq k \leq n/2$ is $\binom{50}{3}$, which we verified in [11] for $n < 10^6$. We also showed there, assuming the abc-conjecture,
that there are, in all, only finitely many pairs of integers \(k, n\) satisfying \(3 \leq k \leq n/2\), for which \(\binom{n}{k}\) is powerful.

It has long been known that if \(d := (2n + 1)^2 - 1\) is squarefree, with \(n > 1\), then the class group of \(\mathbb{Q}(\sqrt{-d})\) contains an element of order \(r\); and, similarly, if \(D := (2N + 1)^2 + 1\) is squarefree, with \(N > 1\), then the class group of \(\mathbb{Q}(\sqrt{D})\) contains an element of order \(R\). As noted by Ram Murty in [18], we can thus deduce from the abc-conjecture, via Theorem 1, quantitative lower bounds for the number of such quadratic fields. Subsequently, Murty [19] cleverly dispensed with the assumption of the abc-conjecture, and even got sharper lower bounds, by finding a more elaborate class of such fields. This allowed him to directly apply the tools of sieve theory.

Murty’s approach to lower bounds for the number of such real quadratic fields amounts to giving a lower bound for the number of distinct values of \(f(n)\) in \(\mathbb{Q}/\mathbb{Q}^2\), with \(1 \leq n \leq N\), for certain polynomials \(f\). From Theorem 1, we immediately deduce the following corollary.

**Corollary 2.** Assume that the abc-conjecture is true, and that \(f(x) \in \mathbb{Z}[x]\) has no repeated roots. Then there are \(\gg_r N\) distinct values of \(f(n)\) in \(\mathbb{Q}/\mathbb{Q}^2\), with \(1 \leq n \leq N\). \(\square\)

We guess that the number of such distinct values is \(\sim c_r N\) for some constant \(c_r \geq c_r > 0\), though we are not sure what \(c_r\) should equal.

The result in Corollary 2 follows unconditionally when \(f\) has degree \(\leq 3\), from the remarks immediately following the statement of Theorem 1. By modifying Murty’s argument in [18], one has, in general, the unconditional lower bound \(\gg_r N / \log^\gamma N\) distinct values of \(f(n)\) in \(\mathbb{Q}/\mathbb{Q}^2\), with \(1 \leq n \leq N\), where \(\gamma_r \geq 1\) is the number of distinct irreducible factors of \(f\): The fundamental lemma of the sieve, together with the Chebotarev density theorem,4 gives that if \(u\) is a sufficiently large, fixed, real number (depending on \(f\)), then there are \(\gg_u \log N\) integers \(n\), with \(N/2 \leq n \leq N\), for which \(f(n)/B\) is free of prime factors \(< N^{1/u}\). Thus, if \(f(n) \in a\mathbb{Q}^2\), for such an integer \(n\), where \(a\) is squarefree, then \(a\) has \(\ll u \deg f + \log B \ll_r 1\) prime factors. Now, Theorem 1b of Evertse and Silverman [7] implies that the number of integer solutions to \(Ax^2 = f(x)\) is bounded as a function of the number of distinct prime factors of \(A\). Therefore, no more than an absolutely bounded number of such \(n\) give rise to the same value of \(f(n)/B\) in \(\mathbb{Q}/\mathbb{Q}^2\), and our result follows.

The proof of the key result, Theorem 5, is an easy consequence of the following.

**Lemma 1.** Given any homogenous \(f(x, y) \in \mathbb{Q}[x, y]\), we can determine homogenous polynomials \(a(x, y), b(x, y), c(x, y) \in \mathbb{Z}[x, y]\), all of degree \(D \geq 1\), without common factors, where:

---

4This is used to estimate the Euler product that arises.
\(a(x, y)b(x, y)c(x, y)\) has exactly \(D + 2\) nonproportional linear factors, including all of the factors of \(f(x, y)\); and \(a(x, y) + b(x, y) = c(x, y)\).

2 Sketch of the proof of Lemma 1

Belyi's theorem [1], [21, p. 71] gives an extraordinary way to test whether a curve is algebraic: Curve \(C\) is algebraic if and only if there exists a rational morphism \(\phi: C \rightarrow \mathbb{P}^1\) which is ramified over only \([0, 1, \infty]\). We shall not use his result, but rather an observation that is a simple modification of part of his proof.

Lemma 2 (Belyi [1]). For any finite subset \(S\) of \(\mathbb{P}^1(\overline{\mathbb{Q}})\), there exists a rational function \(\phi(x) \in \mathbb{Q}[x]\), ramified only over \([0, 1, \infty]\), such that \(\phi(S) \subset [0, 1, \infty]\).

This useful lemma is proved, for instance, by Serre as Theorem B on page 71 of [21] (for variations, see Belyi [1], Elkies [3], Langevin [16], [17], or my own less geometric account in [12]).

Assuming Lemma 2, we now proceed to the proof of Lemma 1. Let \(S = \{(\alpha, \beta) \in \mathbb{P}^1 : f(\alpha, \beta) = 0\}\) and apply Lemma 2, writing \(\phi(x/y) = a(x, y)/c(x, y)\), where \(a(x, y), c(x, y) \in \mathbb{Q}[x, y]\) are homogenous forms, with the same degree as \(\phi\) (call it \(D\)), and without common factors. Let \(b(x, y) = c(x, y) - a(x, y)\). Note that

\[
\begin{align*}
\phi(x/y) &= 0 \quad \text{if and only if} \quad a(x, y) = 0; \\
\phi(x/y) &= 1 \quad \text{if and only if} \quad b(x, y) = 0; \\
\phi(x/y) &= \infty \quad \text{if and only if} \quad c(x, y) = 0.
\end{align*}
\]

Therefore, \(f(x, y)\) divides \(a(x, y)b(x, y)c(x, y)\). If we write \(\#\phi^{-1}(u)\) for the number of distinct \(t \in \mathbb{P}^1(\overline{\mathbb{Q}})\) for which \(\phi(t) = u\), then \(\#\phi^{-1}(0) + \#\phi^{-1}(1) + \#\phi^{-1}(\infty)\) equals the number of distinct linear factors of \(a(x, y)b(x, y)c(x, y)\), by the observation immediately above. On the other hand, applying the Riemann-Hurwitz formula to the map \(\phi: \mathbb{P}^1 \rightarrow \mathbb{P}^1\), we note (since \(\mathbb{P}^1\) has genus zero, and \(\phi\) is ramified only over \([0, 1, \infty]\)) that

\[
2D = 2 + \sum_{u \in [0, 1, \infty]} \{D - \#\phi^{-1}(u)\}.
\]

Thus \(\#\phi^{-1}(0) + \#\phi^{-1}(1) + \#\phi^{-1}(\infty) = D + 2\), which concludes the proof.

3 Proof of Theorem 5

In [3] (around (26)), Elkies notes that his methods allow him to deduce, from the abc-conjecture, that Vojta's conjectured K-analogue of the second main theorem of Nevanlinna...
theory is true for every number field \( K \). Theorem 5 is just the case \( K = \mathbb{Q} \), though the general case requires no further significant ideas. This same circle of ideas, with similar conclusions, appear in a paper of Langevin [17].

We deduce Theorem 5 from Lemma 1 as follows: Apply Lemma 1 and multiply together the distinct irreducible factors of \( a(x, y)b(x, y)c(x, y) \) to get a polynomial \( f(x, y)g(x, y) \) of degree \( D + 2 \).

Let \( k = \gcd(a(m, n), b(m, n)) \), where \( (m, n) = 1 \). It is easy to show that \( k \) divides the resultant of \( a \) and \( b \), which is a nonzero integer, so that \( k \) is bounded. Now we apply the abc-conjecture directly to the equation \( \alpha/k + b/k = c/k \) to get

\[
\max([a(m, n), |b(m, n)|])^{1 - \epsilon} \ll \prod_{p \mid abc} p \prod_{p \mid fg} p \leq g(m, n) \prod_{p \mid (m, n)} p.
\]

Write \( H = H(m, n) = \max(|m|, |n|) \). Note that if \( \alpha \) is fixed, then \( |m - \alpha n| \ll H \). Thus \( |g(m, n)| \ll H^{D+2-\deg(f)} \). Moreover, suppose that \( \alpha \neq \beta \) are fixed. Since \( (m - \alpha n) - (m - \beta n) = (\alpha - \beta)n \), and \( \alpha(m - \beta n) - \beta(m - \alpha n) = (\alpha - \beta)m \), we deduce that \( \max(|m - \alpha n|, |m - \beta n|) \gg H \). Thus, since \( a(x, y), b(x, y) \) have no common factors, \( \max([a(m, n), |b(m, n)|]) \gg H^{1/2} \). The result follows from substituting these two estimates into the equation above.

\[ \blacksquare \]

4 Proofs of Theorems 1 and 2

We begin by proving, in the notation of the theorems, the following propositions.

**Proposition 1.** There are \( \sim cN \) positive integers \( n \leq N \) for which \( f(n)/B' \) is not divisible by the square of a prime \( p \leq N \).

**Proposition 2.** There are \( \sim c'MN \) pairs of positive integers \( m \leq M, \ n \leq N \) for which \( f(m, n)/B' \) is not divisible by the square of a prime \( p \leq \max(M, N) \).

We describe here the proof of Proposition 1; the proof of Proposition 2 is mostly analogous, and we comment later, only on where the proofs significantly diverge.

To say that \( f/B' \) is squarefree means that it is not divisible by the square of any prime \( p \). Thus, in Theorem 1, the number of \( n \leq N \) for which \( f(n)/B' \) is squarefree is equal to: the number of \( n \leq N \) for which \( f(n)/B' \) is not divisible by the square of a prime \( p \leq z \), plus an error term bounded by the sum, over all primes \( p > z \), of the number of integers \( n \leq N \) for which \( f(n)/B' \) is divisible by \( p^2 \).

Now, if prime \( p \) does not divide either \( B \) or the discriminant of \( f \), then \( \omega_f(p) \leq d := \deg(f) \). We select \( z \) larger than \( B \text{disc}(f) \), so that

\[
\sum_{p > z} \frac{\omega_f(p)}{p^{2+\epsilon_p}} \leq d \sum_{p > z} \frac{1}{p^2} \ll \frac{1}{z}.
\]
Selecting $z = (1/3) \log N$, we let $M = \prod_{p \leq z} p^{2+q_p}$; by the prime number theorem, $M = N^{2/3 + o(1)}$. By the Chinese remainder theorem, there are exactly
\[ M \prod_{p \leq z} \left(1 - \frac{\omega_f(p)}{p^{2+q_p}}\right) \]
integers $n$ in any interval $(x, x + M)$, for which $f(n)/B'$ is not divisible by the square of a prime $p \leq z$. Thus there are
\[ (N + O(M)) \prod_{p \leq z} \left(1 - \frac{\omega_f(p)}{p^{2+q_p}}\right) \]integers $n \leq N$ for which $f(n)/B'$ is not divisible by the square of a prime $p \leq z$. By (3), we know that
\[ c_f / \prod_{p \leq z} \left(1 - \frac{\omega_f(p)}{p^{2+q_p}}\right) = 1 + O\left(\frac{1}{z}\right), \]
and so we have proved that there are $\sim c_f N$ integers $n \leq N$ for which $f(n)/B'$ is not divisible by the square of a prime $p \leq z$.

Now, there are $\omega_f(p)(N/p^{2+q_p} + O(1))$ integers $n \leq N$ for which $f(n)/B'$ is divisible by $p^2$, for any given prime $p$. If $p > z$, then this number is $\leq dN/p^2 + O(d)$. Therefore, the number of integers $n \leq N$ for which $f(n)/B'$ is divisible by $p^2$, for some prime $p$ in the range $z < p \leq N$, is
\[ \ll d \sum_{z < p \leq N} \left(\frac{N}{p^2} + 1\right) \ll \frac{N}{z} + \frac{N}{\log N} = o(N). \]
We have therefore proved Proposition 1.

To prove Proposition 2, suppose that $N \geq M$ (the $M > N$ case is handled analogously). Dealing with the primes $p \leq z$ is done entirely analogously: the use of $\omega_f(p)$, as opposed to $\omega_f(p)$, takes account of the slight differences in these cases. For the primes $p > z$, we first remove all pairs $(m, n)$ which have a common prime factor $> z$, and those for which $p^2/m$ for some prime $p > z$. The number of such pairs is $\leq \sum_{p > z} M/N/p^2 \ll MN/z = o(MN)$. Then we use the same argument as was used above for each $f(m, n)$, where $m$ is fixed $\leq M$ and $p^2 \nmid m$ for any $p > z$. We have to be a little careful because the discriminant of $f(m, x)$ may be divisible by some primes which do not divide the discriminant of $f(1, x)$, but all of these primes will divide $m$. However, for such primes $p$, we note that if $p^2$ divides $f(m, n)$, then $p$ divides some nonzero coefficient of $f$ (note that $p$ does not divide $n$, since it already divides $m$). However, this is a finite set of primes, bounded independently of $m$, and thus the above estimates are uniform. Proposition 2 follows.

Now that Propositions 1 and 2 are proved, we can complete the proof of Theorems 1 and 2. We do this by showing that, for any fixed $\varepsilon > 0$, there are $O(\varepsilon N)$ integers
n \leq N for which f(n) is divisible by the square of a prime > N; and similarly, we show that there are O(\varepsilon MN) integers m \leq M, n \leq N for which f(m, n) is divisible by the square of a prime > \max(M, N). Observe that such results are true for f if they are true for all of the irreducible factors of f; thus we will prove such a result assuming that f is irreducible over \mathbb{Z}[x] (or \mathbb{Z}[x, y], respectively). Now the square of any prime p > N is > N^2, so it certainly cannot divide a nonzero value |f(n)| of a linear polynomial f (since it is a lot bigger). In fact, we can alter the proofs of Propositions 1 and 2 to make the conclusions true with all primes p \leq cN (or p \leq c \max(M, N), respectively); choosing c large enough implies that the square of any prime p > cN is greater than |f(m)| (or |f(m, n)|), respectively if f is quadratic. Thus Theorems 1 and 2 are a consequence of the following result (taking N = 1 to prove Theorem 1).

**Theorem 8.** Assume that the abc-conjecture is true. Suppose that f(x, y) \in \mathbb{Z}[x, y] is homogenous and irreducible, of degree d \geq 3. Fix \varepsilon > 0. There are O(\varepsilon MN) pairs of integers m and n, such that f(m, n) is divisible by the square of a prime > \max(M, N).

In Theorem 6, we noted that f(m, n) is not divisible by the square of any integer > \max(M, N)^{2+\varepsilon}. This is not quite enough to deduce Theorem 8, since we need to also rule out slightly smaller primes; that is, as small as \max(M, N). Instead we apply Theorem 6 to a new polynomial,

\[
F(x, y) := f(x, y)f(x + y, y)f(x + 2y, y) \cdots f(x + (k-1)y, y).
\]

\(F(x, y)\) has no repeated factors, for if it did, then we would have roots \(\alpha, \beta\) of \(f(x, 1) = 0\), with \(\beta = \alpha + i\) for some positive integer i. Since \(f\) is irreducible, the Galois group G for its splitting field extension is transitive and so, for any root \(\gamma\) of \(f(\gamma, 1) = 0\), there exists \(\sigma \in G\) for which \(\gamma = \alpha^\sigma\). Select that root \(\gamma\) of \(f(x, 1) = 0\) for which \(\text{Re}(\gamma)\) is maximal. Then \(\beta^\sigma = \alpha^\sigma + i = \gamma + i\), so \(\text{Re}(\beta^\sigma) = \text{Re}(\gamma) + i > \text{Re}(\gamma)\), giving a contradiction.

Assume, for convenience, that \(M > N\). Now, for every \(m' \leq M, n \leq N\) with \((m', n) = 1\), there exists some integer \(m \in M\) such that \(m' = m + in\) for some \(0 \leq i < k\), where \(M\) is the set of integers \(m\) of the form \(m = i + jnk\), where \(0 < i < n, (i, n) = 1, 0 \leq j \leq [M/nk]\). Theorem 5 applied to \(f(m, n)\) for each \(m \in M, n \leq N\) implies\(^5\) that there are at most two \(f(m + in, n), 0 \leq i < k\), which are divisible by the squares of primes > \(M\). Thus, in total, there are \(O(|M|) = O(N^2 + MN/k)\) pairs \(m' \leq M, n' \leq N, (m', n') = 1\) such that \(f(m', n')\) is divisible by squares of primes > \(M\).

\(^5\) Note that if \(q^2\) divides \(f(m, n)\), where \(q > M\), then \(\prod_{p|f(m, n)} p \ll M^{\deg f - 1}\). Thus if three of the \(f(m + in, n)\) were divisible by squares of primes > \(M\), we would have \(\prod_{p|f(m, n)} p \ll M^{\deg f - 3}\), contradicting Theorem 5.
divisible by the square of a prime \( > M \). Selecting \( k = \lfloor 1/\varepsilon \rfloor \) implies Theorem 8, provided \( N = O(\varepsilon M) \).

We would like to apply a similar argument to deduce Theorem 8 when \( M = O(N) \). Let us suppose that we can find some finite set \( \mathcal{J} \) of "distinct" \(^6\) matrices \( \mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}(2, \mathbb{Z}) \), such that for any sufficiently large \( R := \max\{M, N\} \), there exists a set \( \mathcal{L} \) of \( O(\varepsilon^2 R^2) \) lattice points such that

\[
\{(x, y) \in \mathbb{Z}^2 : 1 \leq x, y \leq R, (x, y) = 1\} \subset \bigcup_{(m,n) \in \mathcal{L}} \{(am + bn, cm + dn) : A \in \mathcal{J}\}.
\]

Let

\[
F(x, y) := \prod_{A \in \mathcal{J}} f(Ax), \quad \text{where} \quad Ax := (ax + by, cx + dy).
\]

A priori, we have no reason to believe that we can apply Theorem 5 to \( F(x, y) \), since it may have repeated roots. In the Appendix, we show that, since \( \deg(f) > 2 \), there is a group \( H \) of at most 12 matrices, such that if \( f(x) \) and \( f(Ax) \) have common roots, then \( A \in H \). Let \( \mathcal{J} \) be a subset of the matrices in \( \mathcal{J} \), constructed by selecting exactly one matrix from each orbit \( \{hA : h \in H\}_{A \in \mathcal{J}} \). Then we can apply Theorem 5 to \( G(x, y) := \prod_{A \in \mathcal{J}} f(Ax) \), for each \( (x, y) \in \mathcal{L} \). Proceeding as before, we now have at most \( 2 \times 12 \times |\mathcal{L}| = O(\varepsilon^2 R^2) = O(\varepsilon MN) \) pairs \( 1 \leq m, n \leq R \) with \( (m, n) = 1 \), for which \( f(m, n) \) is divisible by the square of a prime \( > R \), and we have thus proved Theorem 8.

It only remains to show that we can construct such a set \( \mathcal{J} \), and the set \( \mathcal{L} \) of lattice points for any given \( R \): We define

\[
\mathcal{L} := [1, \varepsilon R] \times [1, \varepsilon R] \bigcup [1, \varepsilon^2 R] \times [1, R] \bigcup [1, R] \times [1, \varepsilon^2 R]
\]

and \( \mathcal{J} \) to be the set of all "free words"\(^7\) of length \( \leq [2/\varepsilon^2] \) on the matrices \( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \) and \( \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} \).

We need to show that for every \((x, y) \in [1, R] \times [1, R] \), where the \( \gcd(x, y) = 1 \), there is some \( A \in \mathcal{J} \), such that \( A^{-1}(x, y) \in \mathcal{L} \). We will construct \( A^{-1} \), which will be a free word of length \( \leq [2/\varepsilon^2] \) on \( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \) and \( \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} \). We now describe our algorithm to construct \( A^{-1} \), as follows.

Take \( A = I \) for all \((x, y) \in \mathcal{L} \). Otherwise, we may assume \( x, y > \varepsilon^2 R \). The matrices correspond to the transformations \((x, y) \to (x - y, y) \) and \((x, y) \to (x, y - x) \) (note that both maps keep \( \gcd(x, y) = 1 \) fixed). We select the first map if \( x > y \), and we select the latter map if \( x < y \) (note \( x = y \) implies we have the point \((1, 1)\)). The new lattice point is also inside the top right quadrant, and the sum of its ordinates has been reduced by at least \( \varepsilon^2 R \). We repeat this process until the transformed lattice point is in \( \mathcal{L} \). This must happen within \([2/\varepsilon^2]\) iterations of our algorithm; otherwise the transformed lattice point is still

\(^6\) We take \( \gcd(a, b, c, d) = 1 \), without loss of generality, and thus ensure that the matrices are distinct in \( \text{PGL}(2, \mathbb{Z}) \).

\(^7\) That is, all expressions of the form \( XYYYYYYYYY...YY \), with the \( X \)'s and \( Y \)'s in any order.
in the top right quadrant, and the sum of itsordinates is \( \leq R + R - [2/\varepsilon^2]\varepsilon R < \varepsilon^2 R \), which means that it is in \( L \).

5 Proof of Theorem 3, assuming Theorem 6

We proceed much as in the previous section: Let \( k = [9/\varepsilon] \) and define \( g(t) = (t + 1)(t + 2)(t + 3) \ldots (t + k) \).

Using the sieve of Eratosthenes, one knows that there are

\[
\sim \frac{6}{\pi^2} x^{1-\varepsilon} < \frac{2}{3} x^\varepsilon
\]

integers in the interval \((x, x + x^\varepsilon)\) which are not divisible by the square of a prime \( \leq x^\varepsilon \). Thus, if there are to be no squarefree integers in this interval, then there must be at least \((1/3)x^{1-\varepsilon}\) integers \( m \in (x, x + x^\varepsilon) \) divisible by the square of a prime \( > x^\varepsilon \). But that means there is an integer \( m \in (x, x + x^\varepsilon) \) such that at least one-quarter of the integers \((m+1), (m+2), \ldots, (m+k)\) are divisible by the square of a prime \( > x^\varepsilon \). Thus \( g(m) \) is divisible by the square of an integer \( > (x^\varepsilon)^{k/4} > m^2 \), contradicting Theorem 6.

6 Proof of Theorem 4

As we noted in the Introduction, Theorem 4 follows once we prove (2), which we will now do. By adjusting the constant in (2) as necessary, we can assume that \( T \) is sufficiently large. By Theorem 3, we know that \( S(x; t) = 0 \) when \( t \gg x^\varepsilon \), in particular, when \( t \geq x^{1/2A(A+1)} \), and \( x \) is sufficiently large. Thus we will prove (2), assuming that \( 2(A + 2)^2 \leq T < x^{1/2A(A+1)} \).

Let \( B \) be the smallest integer \( \geq A \).

We begin by noting that, by the sieve of Eratosthenes, there are \( \geq (3/5)t \) integers in any interval of length \( t \geq T \), which are not divisible by the square of any prime \( \leq 2T \) (note that \( 3/5 < 6/\pi^2 \)).

Let \( S'(x; T) \) count the number of \( s_n \leq x \) with \( T \leq s_{n+1} - s_n < 2T \), for which there are \( \geq T/2 \) integers in the interval \((s_n, s_{n+1})\) which are not divisible by the square of any prime \( \leq 2T \) or \( > T^A \). Note that for any \( s_n \leq x \) counted by \( \sum_{T \leq t < 2T} S(x; t) \) but not by \( S'(x; T) \), there must be \( > T/10 \) integers \( m \in (s_n, s_{n+1}) \) which are divisible by the square of some prime \( > T^A \). Therefore,

\[
\frac{T}{10} \left( \sum_{T \leq t < 2T} S(x; t) - S'(x; T) \right) \leq \sum_{m \leq x} \sum_{p > T^A} \sum_{m^2 | p^{2n} m} \frac{1}{p^{2n}} \ll \frac{x}{T^A}.
\]

This contribution to the sum in (2) is acceptably small.
If \( s_n \) is counted by \( S'(x; T) \), then there are \( \geq 1 \) integers in the interval \((s_n, s_{n+1})\) divisible by the square of a prime in the range \([2T, T^A]\). Thus there are at least \( \binom{T/2}{B} \) different \( B \)-tuples of integers of the form

\[
s_n < k_1 p_1^2 < k_2 p_2^2 < \cdots < k_B p_B^2 < s_{n+1},
\]

where the \( p_j \) are distinct primes from \([2T, T^A]\). Note that we can write \( k_j p_j^2 = k_j p_j^2 + d_j \) for \( 2 \leq j \leq B \), where \( 1 \leq d_2 < d_3 < \cdots < d_B \leq 2T \). Taking together all such \( B \)-tuples from all of the \( s_n \) counted by \( S'(x; T) \), we get

\[
S'(x; T) \left( \binom{T/2}{B} \right) \leq \sum_{\substack{2T < p_1, p_2, \ldots, p_B < T^A \text{ distinct} \\ k_1 p_1^2 \leq x \\ k_1 p_1^2 = k_1 p_1^2 + d_1 \text{ for } 2 \leq j \leq B}} \sum_{1 \leq d_2 < d_3 < \cdots < d_B \leq 2T} 1.
\]

Let us concentrate on the last sum first. If we let \( \tau = k_1 p_1^2 \), then we see that \( \tau \equiv 0 \pmod{p_1^2} \), and \( \tau \equiv -d_j \pmod{p_j^2} \) for \( 2 \leq j \leq B \). Thus \( \tau \) is in some fixed residue class \( \tau_0 \pmod{(p_1 p_2 \ldots p_B)^2} \). There are \( \leq x/(p_1 p_2 \ldots p_B)^2 + 1 \) such integers \( \tau \leq x \); this quantity is \( \leq 2x/(p_1 p_2 \ldots p_B)^2 \) since \( (p_1 p_2 \ldots p_B)^2 \leq T^{2A(B-1)} < x \). Noting also that there are precisely \( (2T-1) \) choices for the \( d_j \) in the sum above, we get

\[
S'(x; T) \left( \binom{T/2}{B} \right) \ll \sum_{\substack{2T < p_1, p_2, \ldots, p_B < T^A \text{ distinct}}} \left( \frac{2T}{B-1} \right) \frac{2x}{(p_1 p_2 \ldots p_B)^2} \ll x T^{B-1} \left( \sum_{p \geq 2T} \frac{1}{p^2} \right)^B \ll \frac{x}{T},
\]

which implies (2).

**Appendix: Fractional linear transformations of roots of an irreducible polynomial**

Let \( f(x) \in \mathbb{Z}[x] \) be an irreducible polynomial of degree \( d \geq 2 \). We wish to determine all fractional linear transformations (that is, elements of \( \text{PGL}(2, \mathbb{Q}) \)), which send some root of \( f \) to some other root of \( f \).

All such transformations are of the form

\[
\beta = \frac{ax + b}{cx + d},
\]

with \( a, b, c, d \in \mathbb{Z} \). Applying any element \( \sigma \) of the Galois group gives

\[
\beta^\sigma = \frac{ax^\sigma + b}{cx^\sigma + d}.
\]

Since the Galois group, \( G \), is transitive, the action of the linear transformation defines a permutation of all the roots of \( f \). Since we can compose permutations, we see that our transformations form a group; we call it \( H = H_f \).
Quadratic polynomials: $d = 2$

Make a change of variable of the form $x \to x + a$ to guarantee that $f(x)$ is of the form $x^2 - m$, where $m$ is not a square.\(^8\) Such a transformation which sends $\sqrt{m} \to \pm \sqrt{m}$ gives

$$\frac{a \sqrt{m} + b}{c \sqrt{m} + d} = \pm \sqrt{m}.$$  

Multiplying through by the denominator, we obtain $a \sqrt{m} + b = \pm (cm + d \sqrt{m})$ so that $b = \pm cm$ and $a = \pm d$. Thus the set of such transformations are given by the matrices

$$\begin{pmatrix} \pm d & \pm cm \\ c & d \end{pmatrix}, \quad (c, d) \in \mathbb{P}^1(\mathbb{Q}).$$

$H$ is isomorphic to the group (under multiplication) $\{d + c \sqrt{m}/\mathbb{Q}\}^*$ with $c, d \in \mathbb{Q}$, and thus has infinite rank.

Higher degree polynomials: $d \geq 3$

Suppose now that $(a \alpha + b)/(c \alpha + d) = \alpha$, where $\alpha$ is a root of $f$. Then $c \alpha^2 + (d - a) \alpha - b = 0$. But $\alpha$ is a root of an irreducible polynomial of degree $> 2$, so we must have $c = a - d = b = 0$; that is, our linear transformation is the identity map (as a matrix it is the identity in $\text{PGL}(2, \mathbb{Q})$).

Now if $\alpha \in H$, each $\alpha^r$ gives a root of $f$; and since there are $d$ different roots, we must have $A \alpha = A^s \alpha$ (say) for some $0 \leq r < s \leq d$. Therefore $A^n \beta = \beta$, where $n = s - r$, and so $A^n$ is the identity map by what we proved in the paragraph above. In particular, we see that $A$ is invertible.

If $A, B \in H$ and $A \alpha = B \alpha$ (say), then $AB^{-1} \beta = \beta$, so $AB^{-1}$ is the identity, so $A = B$. Therefore, since the $A \alpha$ must be distinct, $H$ can have no more than $d$ elements. Thus we see that $H$ is a finite subgroup of $\text{PGL}(2, \mathbb{Q})$; all such subgroups can be identified as follows.

**Proposition A.** The finite subgroups of $\text{PGL}(2, \mathbb{Q})$ are precisely $1, C_2, C_3, C_4, C_6, D_{2 \times 2}, D_{2 \times 3}, D_{2 \times 4}$, and $D_{2 \times 6}$. \(\square\)

All the groups listed in Proposition A do occur as subgroups of $\text{PGL}(2, \mathbb{Q})$. Explicitly, $D_{2 \times n} := \{A_n \cong B^2 = 1; A_nBA_n = B\}$, where $B: z \to 1/z$, and $C_n$ is generated by $A_n$, where

$$A_2 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad A_3 = \begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix}, \quad A_4 = \begin{pmatrix} 1 & 5 \\ -5 & 7 \end{pmatrix}, \quad \text{and} \quad A_6 = \begin{pmatrix} 2 & 1 \\ -1 & 1 \end{pmatrix}.$$

\(^8\) Note that the transformation $x \to x + a$ is itself a fractional linear transformation, so we do this without any loss of generality, since we can compose such transformations.
Realizing the finite subgroups of $\text{PGL}(2, \mathbb{Q})$ as $H_f$

Note that $H_f = C_1$ for $f(z) = z^3 - 2$, and $H_f = C_2$ for $f(z) = z^4 - 2$, where the element in $C_2$ of order 2 is given by the involution $z \rightarrow -z$. It is easy to construct examples when $|H| = 1$ or 2, by any ad hoc method.

Given one of the groups $H$ in Proposition A, of order at least 3, can we find polynomials $f$ with $H_f = H$? Dan Abramovich pointed out to the author that if we have a rational map $\phi: \mathbb{P}^1 \rightarrow \mathbb{P}^1/H$, and we take a set $S$ of roots of some given polynomial $g$, then, in all but finitely many cases, $\phi^{-1}(S)$ will be the set of roots of some polynomial $f$ with $\deg f = |H| \deg g$. An argument can be made that "typically," if $g$ is irreducible, then $f$ will also be irreducible.\(^9\) It is easy enough to make Abramovich's idea concrete in our finitely many cases, that is, to find examples of irreducible $f$ of degree $|H|$ with $H_f = H$, when $|H| \geq 3$, as follows.

In order to force $f$ to be irreducible of degree $|H|$, we take $S$ to contain one element. We wish to write $\phi$ as an invariant rational function of degree $|H|$; the obvious function to try is the trace, $\phi(z) := \sum_{h \in H} hz$. This usually worked, though occasionally there was some cancellation between terms,\(^10\) in which case we instead used $\phi(z) := \sum_{h \in H} (hz)^2$ (whether there is such cancellation depends on which particular explicit representation of $H$ in $\text{PGL}(2, \mathbb{Q})$ one uses in the calculations).

For the cyclic group $H = C_n$, we write $\phi(z) = u(z)/cv(z) := \sum_{h \in H} hz$, where $u$ and $v$ are monic without common roots, and $c$ is a constant. Evidently, the roots of $f(z) = u(z) - jv(z)$ are permuted by $H$, and $u(z) - jv(z)$ is irreducible for "almost all" $j$, by Hilbert's irreducibility theorem. Thus if $C_n$ is generated by $M_n$, then we get $f_n$, as below:

$$M_3 := \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}, \quad M_4 := \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \quad \text{and} \quad M_6 := \begin{pmatrix} 2 & 1 \\ -1 & 1 \end{pmatrix},$$

with

$$f_3(z) = (z^3 - 3z - 1) - jz(z + 1),$$

$$f_4(z) = (z^2 - 2z - 1)(z^2 + 2z - 1) - j(z^3 - z), \quad \text{and}$$

$$f_6(z) = (z^3 + 3z^2 - 1)(z^3 - 3z^2 - 6z - 1) - j(z - 1)(z + 1)(z + 2)(2z + 1).$$

We followed the same strategy with $D_{2 \times 4}$ (generated by $B$ and $A_4$ as above) to obtain

$$f_{2 \times 4} := 175 + 2900z^2 - 16320z^3 + 26746z^4 - 16320z^5 + 2900z^6 + 175z^8 - jz(z + 5)(3z - 5)(5z + 1)(5z - 3)(7z - 7)(7z - 5).$$

\(^9\)"Typically" can be made more precise via the Hilbert irreducibility theorem.

\(^10\)For example, if the map $z \rightarrow -z$ is in $H$, then $\sum_{h \in H} hz = 0$. 

For the other dihedral groups, we found that there was cancellation in \( \sum_{\text{heH}} \text{hz} \), and so we had to replace it in the above computations by \( \sum_{\text{heH}} (\text{hz})^2 \)—this worked on the three remaining occasions, and we obtained

\[
\begin{align*}
\text{f}_{2 \times 2}(z) &= z^4 + 1 - jz^2, \\
\text{f}_{2 \times 3}(z) &= (z^2 - z + 1)^3 - jz^2(z - 1)^2, \quad \text{and} \\
\text{f}_{2 \times 6}(z) &= 4 + 24z + 72z^2 + 140z^3 + 285z^4 + 564z^5 + 738z^6 + 564z^7 + 285z^8 \\
&\quad + 140z^9 + 72z^{10} + 24z^{11} + 4z^{12} - j((z - 1)z(z + 1)(z + 2)(2z + 1))^2.
\end{align*}
\]

(The class of polynomials \( f_{2 \times 3}(z) \) are familiar from the construction of the \( \lambda \)-invariant of elliptic curves out of the \( j \)-invariant.)

The finite subgroups of \( \text{PGL}(2, \mathbb{Q}) \): Proofs

To prove that no groups \( H \) can occur, other than those listed in Proposition A, we use Serre’s result ([20, Proposition 16]): If \( H \) is a finite subgroup of \( \text{PGL}(2, k) \), where \( k \) is a field whose characteristic is coprime with the order of \( H \), then the only possibilities for \( H \) are the cyclic groups \( C_n \), the dihedral groups \( D_{2n} \), the alternating groups \( A_4 \) or \( A_5 \), and the symmetric group \( S_4 \). Moreover, he remarks on the same page that if the characteristic of \( k \) is not 2, then \( A_4 \) and \( S_4 \) are subgroups of \( \text{PGL}(2, k) \) if and only if \(-1 \) is the sum of two squares in \( k \); and \( A_5 \) is a subgroup of \( \text{PGL}(2, k) \) if and only if, in addition, \(-5 \) is a square in \( k \).

Thus we note that none of \( A_4, A_5, S_4 \) are subgroups of \( \text{PGL}(2, \mathbb{Q}) \), or even \( \text{PGL}(2, \mathbb{R}) \), by Serre’s criterion. We are therefore left with the cyclic and dihedral groups. To complete the proof of Proposition A, we will prove the following lemma.

**Lemma A1.** If matrix \( A \) has finite order \( n \) in \( \text{PGL}(2, \mathbb{Q}) \), then \( n = 1, 2, 3, 4, \) or 6.

Proof of Lemma A1. A matrix \( A \) of finite order \( n \) in \( \text{PGL}(2, \mathbb{Q}) = \text{PGL}(2, \mathbb{Z}) \) satisfies an equation \( A^n = \lambda I \), with \( \lambda \in \mathbb{Z} \), as well as the quadratic equation \( A^2 - TA + D = 0 \), where \( T = \text{Trace}(A) \) and \( D = \text{Determinant}(A) \) are both integers. Thus the minimal polynomial, \( m(x) \), for \( A \) divides both \( x^2 - Tx + D \) and \( x^n - \lambda \).

If \( m(x) \) has degree 1, then \( A = I \) in \( \text{PGL}(2, \mathbb{Q}) \), so that \( n = 1 \) and \( T^2 = 4D \).

So now assume that \( m(x) \) has degree \( \geq 2 \); since it divides \( x^2 - Tx + D \), we must have that \( m(x) = x^2 - Tx + D \) divides \( x^n - \lambda \). Thus the roots of \( m(x) \) are distinct (since the roots of \( x^n - \lambda \) are distinct). We see that \( n = 2 \) if and only if \( T = 0 \).

So now assume \( n \geq 3 \) so that \( T \neq 0 \). Let \( \rho = |\lambda|^{1/n} \). The roots of \( x^2 - Tx + D \) must be of the form \( \zeta \rho \) and \( \xi \rho \), where \( \zeta \) and \( \xi \) are \( 2n \)-th roots of unity. Then \( \zeta + \xi = T/\rho \neq 0 \) is...
real, and so $\xi = \overline{\zeta}$. Therefore $D = \rho^2$ and thus $\xi^2 + \overline{\zeta}^2 = T^2/D - 2$. The left-hand side of this equation gives that this is an algebraic integer; the right-hand side gives that it is rational; and so it must be a rational integer. Since $|\xi^2 + \overline{\zeta}^2| \leq 2$, we see that the integer must be $-2, -1, 0, 1, 2$, and thus $T = 0$, or $T^2 = D, 2D, 3D, 4D$. This leads to the three following cases: $x^2 + x + 1$ divides $x^3 - 1$; $x^2 + x + 1/2$ divides $x^4 + 1/4$; and $x^2 + x + 1/3$ divides $x^6 + 1/27$, so that we can have $n = 3, 4, 6$, respectively. In fact, we have proved slightly more than previously claimed.

**Lemma A1'.** If $A$ has finite order $n$ in $\text{PGL}(2, \mathbb{Q})$, then $D = \text{Determinant}(A) \neq 0$. In fact, for $T = \text{Trace}(A)$, we have $n = 1$ if and only if $T^2 = 4D$; $n = 2$ if and only if $T = 0$; $n = 3$ if and only if $T^2 = D$; $n = 4$ if and only if $T^2 = 2D$; and $n = 6$ if and only if $T^2 = 3D$.

**Remark.** In a 4 July 1998 e-mail correspondence, Serre remarks that $C_n$ and $D_{2 \times n}$ are subgroups of $\text{PGL}(2, k)$, where $k$ is a field of characteristic 0 if and only if $\xi + \overline{\zeta} \in k$, where $\xi$ is a primitive $n$-th root of unity. Note that, by combining this with Serre's results from [20], Proposition A follows as an immediate consequence.

To prove this for $C_n$, Serre improves on our proof of Lemma A1, obtaining his criterion by noting that $T^2/D = z + \overline{z} + 2$, where $z$ is actually a primitive $n$-th root of unity. He then extends this to $D_{2 \times n}$ by showing, via an explicit matrix construction, that if $A$ represents a semisimple element of $\text{PGL}(2, k)$, then there is an inner automorphism of that group, of order 2, which transforms $A$ to its inverse.

**An observation**

Note that any linear transformation $A \in \text{PGL}(2, \mathbb{Q})$ and any field automorphism $\sigma$ obviously commute. Thus if there is some $\sigma \in G$ and $A \in H$ which have the same "action" on the roots of $f$ (that is, $A\alpha = \sigma \alpha$ for all roots $\alpha$), then $\sigma$ must lie in the center of $G$, and $A$ in the center of $H$. Of the groups listed in Proposition A: $1, C_2, C_3, C_4, C_6, D_{2 \times 2}$ are all commutative; $D_{2 \times 3}$ has trivial center; and $D_{2 \times 4}$ and $D_{2 \times 6}$ have center $C_2$.

**Acknowledgments**

I would like to give special thanks to Dan Abramovich and Jean-Pierre Serre for their observations included in the Appendix. I would also like to thank Malcolm Adams, Dave Benson, Elham Izadi, Will Kazem, Dino Lorenzini, Robert Rumely, and Ted Shifrin for useful conversations pertaining to that section.
